Domain Modelling using UML

Prepared by Dr. Robert Clifton-Everest

Updated by Dr. Ashesh Mahidadia

Domain Models

- Domain Models are used to **visually represent** important domain **concepts** and **relationships** between them.
- Domain Models help **clarify** and **communicate** important domain specific concepts and are used during the requirements gathering and *designing phase*.
- **Domain modeling** is the activity of expressing related domain concepts into a domain model.
- Domain models are also often referred to as *conceptual models* or *domain object models*.
- We will be use Unified Modeling Language (**UML**) **class diagrams** to represent domain models.
- There are many different modelling frameworks, like: UML, Entity-Relationship, Mind maps, Context maps, Concept diagrams. etc.

Requirements Analysis vs Domain modelling

- Requirements analysis determines *external behaviour*
“*What are the features of the system-to-be and who requires these features (actors)*”
- Domain modelling determines (internal behavior) –
“*how elements of system-to-be interact to produce the external behaviour*”
- Requirements analysis and domain modelling are **mutually dependent** - domain modelling supports clarification of requirements, whereas requirements help building up the model.

What is a domain?

- *Domain* – A sphere of knowledge particular to the problem being solved
- *Domain expert* – A person expert in the domain
- For example, in the domain of cake decorating, cake decorators are the domain experts

Problem

A motivating example:

- Tourists have schedules that involve at least one and possibly several cities
- Hotels have a variety of rooms of different grades: standard and premium
- Tours are booked at either a standard or premium rate, indicating the grade of hotel room
- In each city of their tour, a tourist is booked into a hotel room of the chosen grade
- Each room booking made by a tourist has an arrival date and a departure date
- Hotels are identified by a name (e.g. Melbourne Hyatt) and rooms by a number
- Tourists may book, cancel or update schedules in their tour

Ubiquitous language

- **Things in our design must represent real things in the domain expert's mental model.**
- For example, if the domain expert calls something an "order" then in our domain model (and ultimately our implementation) we should have something called an Order.
- Similarly, our domain model should not contain an OrderHelper, OrderManager, etc.
- Technical details do not form part of the domain model as they are not part of the design.

Noun/verb analysis

- Finding the ubiquitous language of the domain by finding the **nouns** and **verbs** in the requirements
- The **nouns** are possible entities in the domain model and the **verbs** possible behaviours

Problem

- The **nouns** and **verbs**:
 - **Tourists** have **schedules** that involve at least one and possibly several **cities**
 - **Hotels** have a variety of **rooms** of different **grades**: standard and premium
 - **Tours** are **booked** at either a standard or premium rate, indicating the **grade** of hotel **room**
 - In each **city** of their **tour**, a **tourist** is **booked** into a hotel **room** of the chosen **grade**
 - Each room **booking** made by a tourist has an arrival **date** and a departure **date**
 - **Hotels** are identified by a **name** (e.g. Melbourne Hyatt) and **rooms** by a **number**
 - **Tourists** may **book**, **cancel** or **update** **schedules** in their **tour**

UML Class diagrams

- Classes

- Relationships

UML Class diagrams

Dependency 

- The loosest form of relationship. A class in some way *depends* on another.

Association 

- A class "uses" another class in some way. When undirected, it is not yet clear in what direction dependency occurs.

Directed
Association 

- Refines association by indicating which class has knowledge of the other

UML Class diagrams

Aggregation

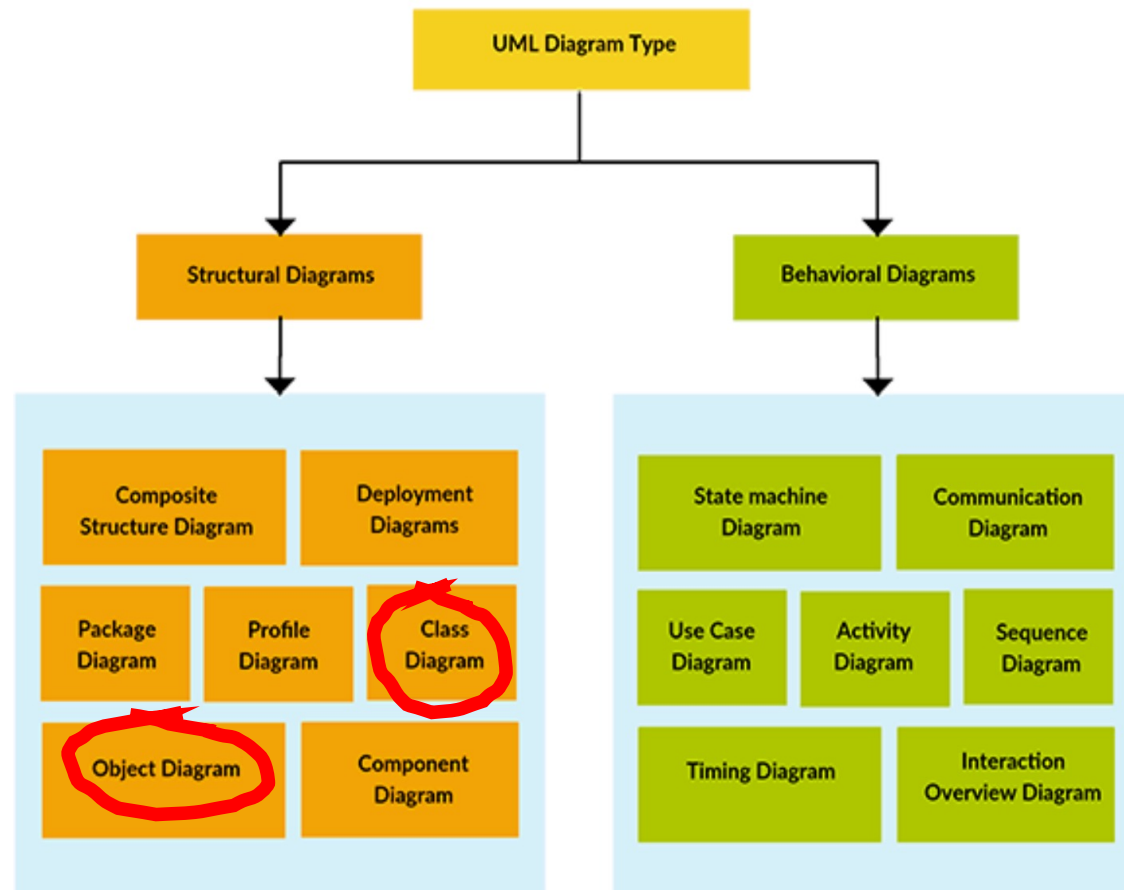

- A class contains another class (e.g. a course contains students). Note that the diamond is at the end with the containing class.

Composition

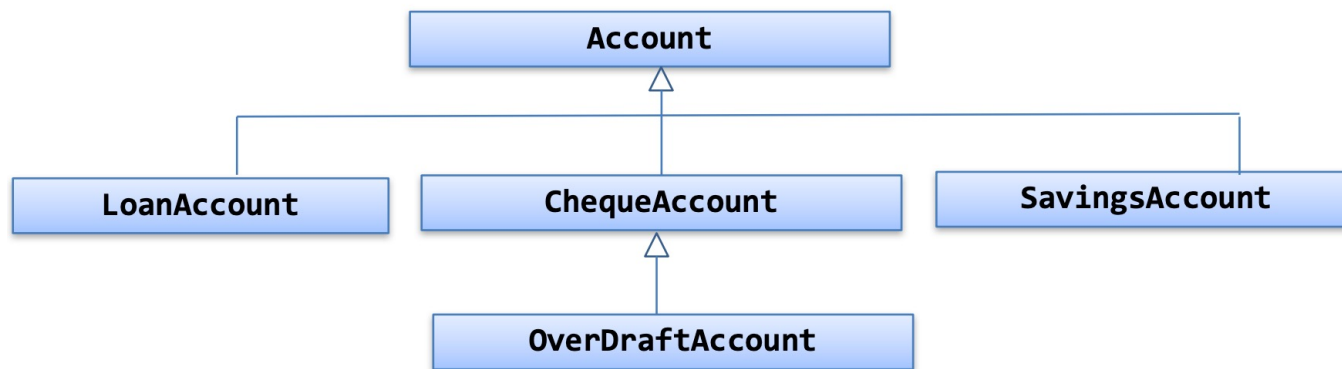

- Like aggregation, but the contained class is integral to the containing class. The contained class cannot exist outside of the container (e.g. the leg of a chair)

UML Diagram Types

Examples

Representing classes in UML

class (class diagram)

Account

-name: String
-balance: float

+getBalance(): float
+getName() : String
+withdraw(float)
+deposit(float)

object instances (object diagram)

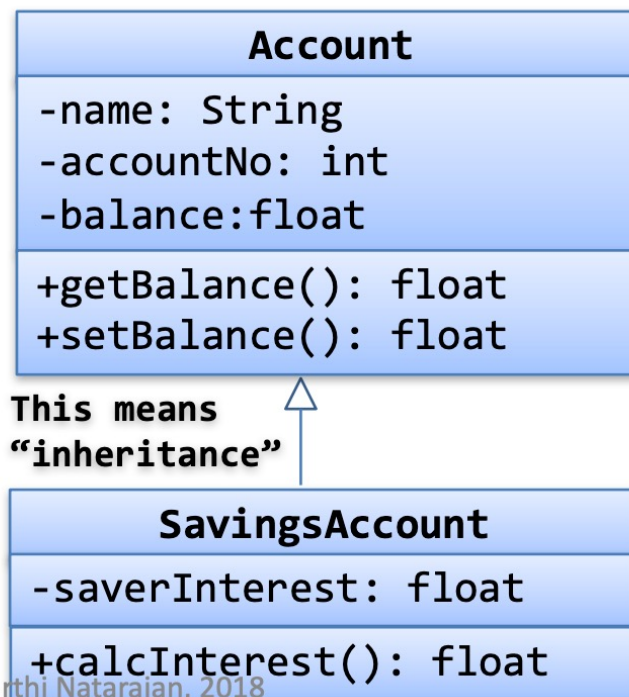

a1:Account

name = "John Smith"
balance = 40000

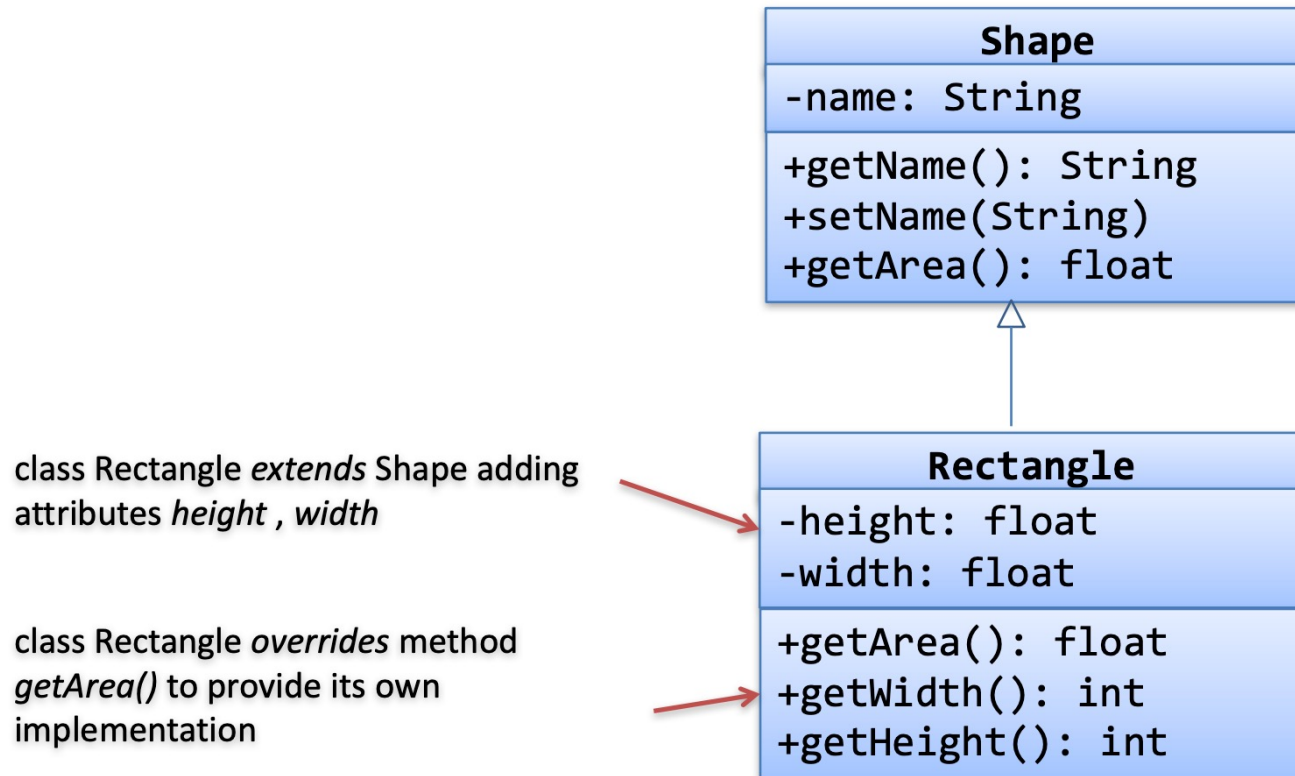

a2:Account

name = "Joe Bloggs"
balance = 50000

Representing classes in UML

Representing Association in UML

© Aarthi Natarajan, 2018

Representing Association in UML

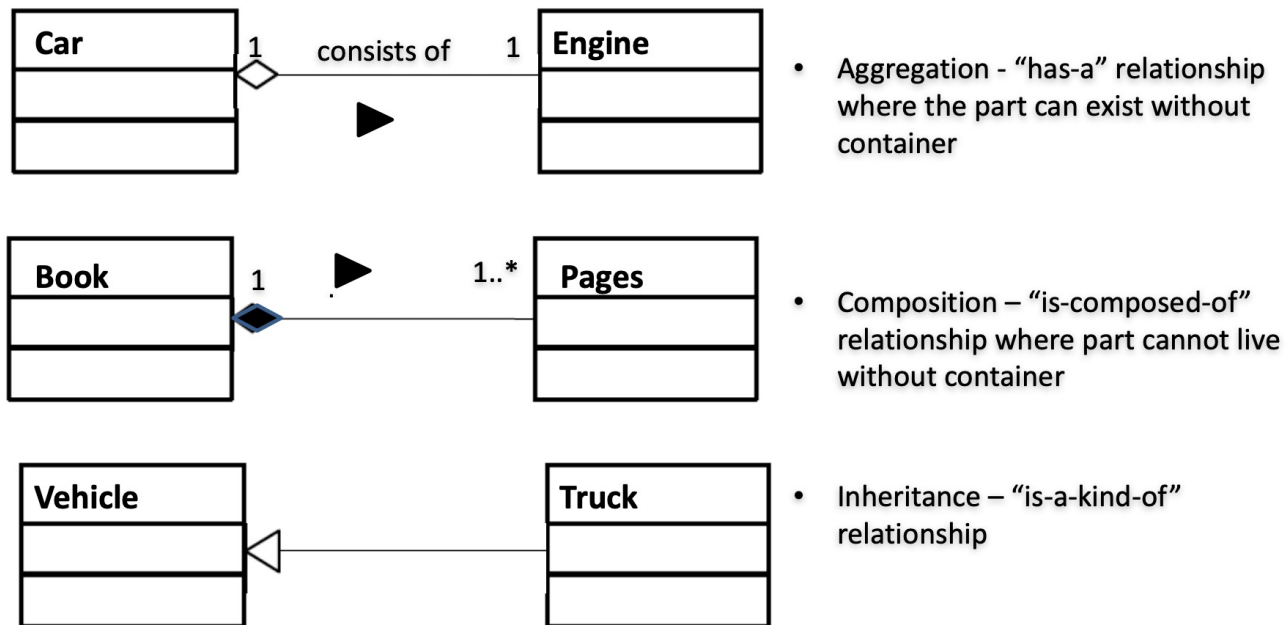

- Associations can model a ***“has-a”*** relationship where one class “contains” another class
- Associations can further be refined as:
Aggregation relationship (hollow diamond symbol ◇): The contained item is an element of a collection but it can also exist on its own, e.g., a lecturer in a university or a student at a university

Composition relationship (filled diamond symbol ◆ in UML diagrams): The contained item is an integral part of the containing item, such as a leg in a desk, or engine in a car

Representing Association in UML

Attributes vs. Classes

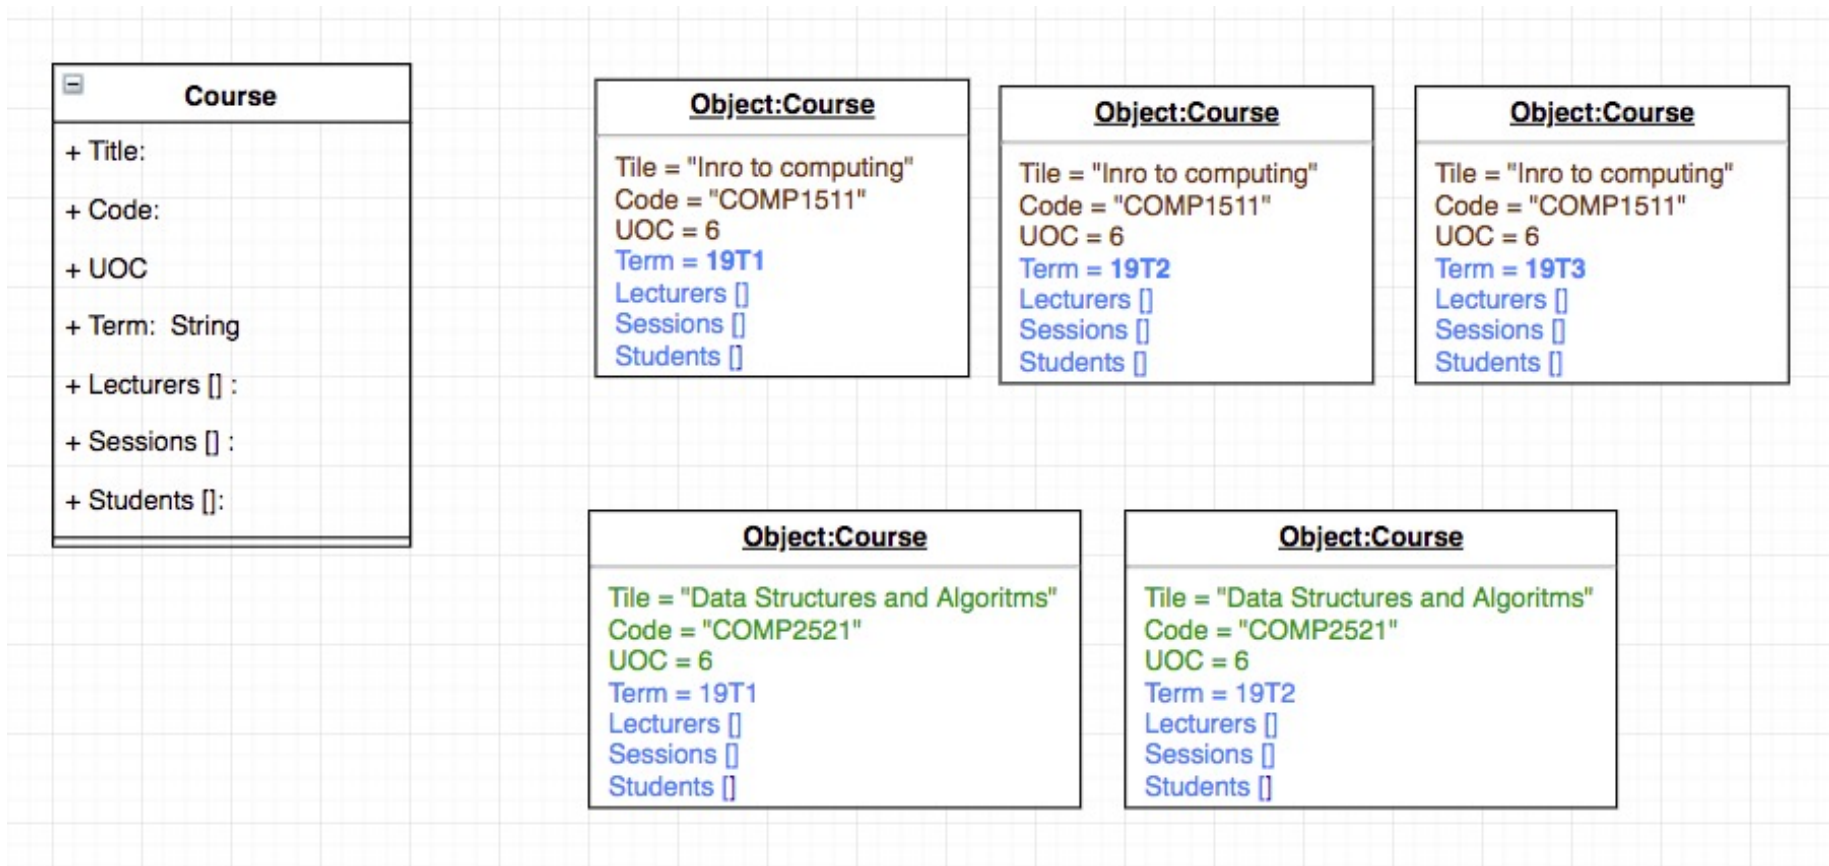

- The most common confusion – *should it be an attribute or a class?*
- when creating a domain model is to represent something as an attribute when it should have been a conceptual class.
- If a concept is not representable by a number or a string, most likely it is a class.
- For example: a *lab mark (attribute)* vs a *student (class)*

Attributes vs. Classes

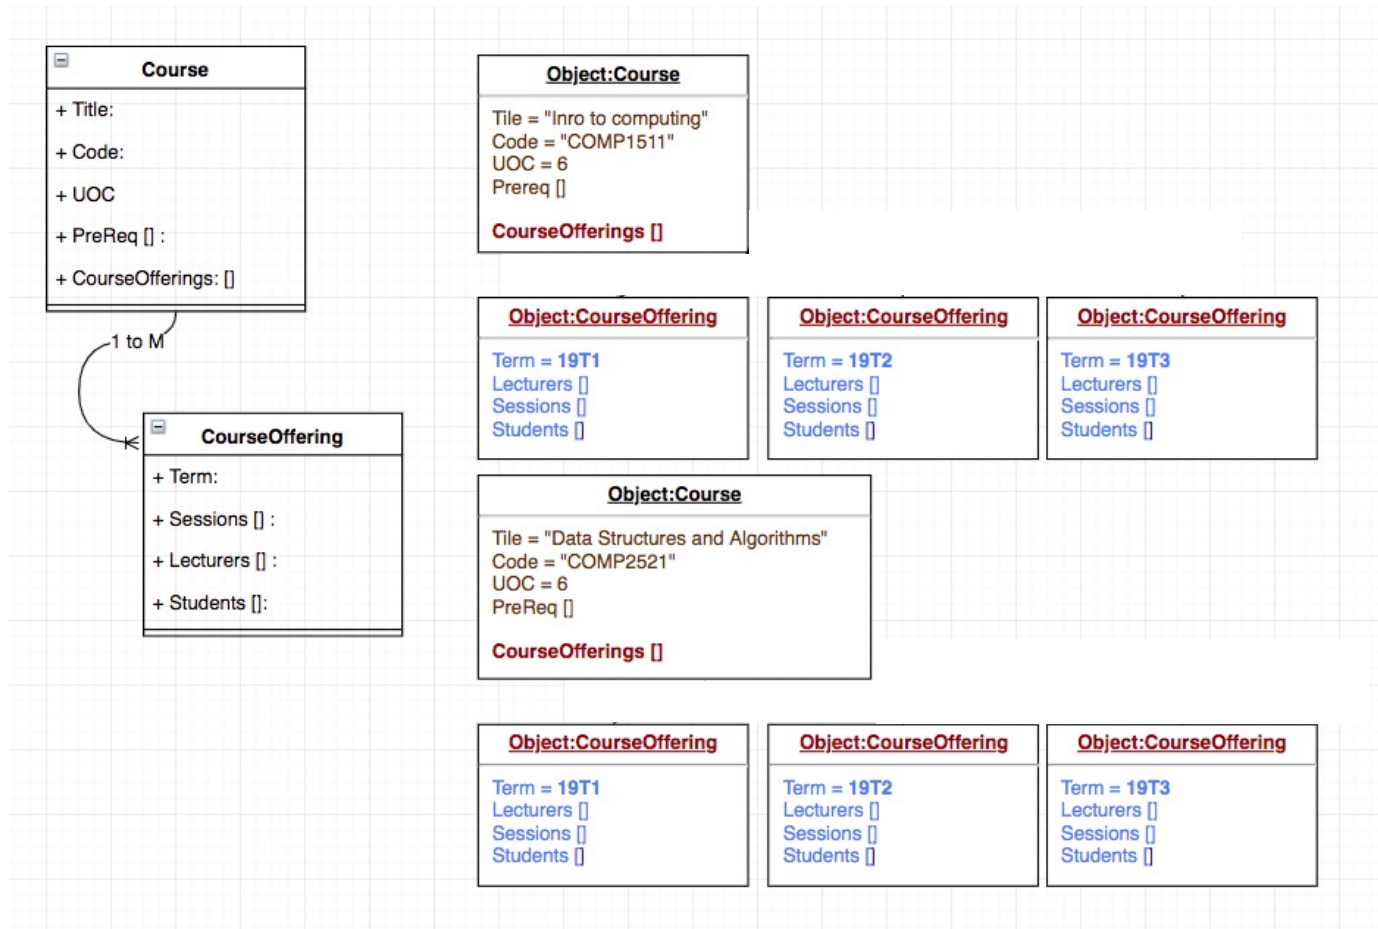

(From <https://homepages.fhv.at/thjo/lecturenotes/sysan/domain-modeling.html#attributes-vs.-classes>)

What wrong with the following?

A Possible solution
